## Problem Statement

- Motivation: RNA RNA interactions (RRI) play important role in various biological process such as gene transcription
- Known to play a critical role in diseases such as Cancer and Alzheimer's
- Necessitating efficient computational tools
- Problem: We choose one of the simpler RRI - BPMax for optimization on CPU
- BPMax - High complexity $\left(\Theta\left(N^{3} M^{3}\right)\right.$ in time and $\Theta\left(N^{2} M^{2}\right)$ in space $)$ makes it both essential and a challenge to parallelize
- Long-term goal: Build efficient libraries for similar RRI algorithms.
- Typical Approach: RRI programs are developed and optimized by hand
- Prone to human error, and costly to develop and maintain
- Our approach: Use a polyhedral compilation tool - $\boldsymbol{A L P H A Z}$, that takes user-specified mapping directives and automatically generate optimized code in C

## Contribution

## - Speedup:

- 100x over the original program
- 170 x for the most compute intensive part $\left[\Theta\left(\mathrm{N}^{3} \mathrm{M}^{3}\right)\right]$
- $1.5 \mathrm{x}-2 \mathrm{x}$ improvement over a similar kernel optimized previously

## - Performance on Xeon E5 1250v4:

- 76 GFLOPS single-precision (for entire program)
- 117 GFLOPS (for most compute-intensive part)
- One-third of the machine peak
- Scales up with more compute power

## - Lines of Code Metric

- Original un-optimized hand-written version - 140
- Final optimized version - 1400

Single-precision performance

## BPMax Overview

## BPMax Overview

- BPMax computes a dynamic programming table to capture interactions between two RNAs
- It uses weighted base-pair counting for base-pair maximization
- Input
- Two sequences of length M and N
- Output
- A four-dimensional triangular table
- A triangular collection of triangles

BPMax Cases

## Methodology Highlights

## Polyhedral Model \& ALPHAZ - Overview

- Polyhedral Model: Mathematical framework for automatic optimization and parallelization of affine programs
- ALPHA: Equational polyhedral programming language
- Affine dependence
- Polyhedral domains
- Reductions with associative commutative operators
- ALPHAZ: Tool that allows the user to explore code generation of ALPHA programs using various-
- Schedules
- Memory-maps
- Parallelization approaches
- Tiling

## Code Generation Methodology

- Typical Polyhedral code generator
- No user intervention beside input programs(c sources)
- Not always optimal
- ALPHAZ
- User specifies polyhedral transformations to the tool
- Allows larger exploration space

## ALPHAZ Transformations Overview

- Normalize:
- Normalizes the program
- Provides better readability

## - NormalizeReduction:

- Transform specified reduction into Normal form
- Reduce expression is a direct child of the equation
- Key target mapping transformations for schedule code generation
- setSpaceTimeMap: Specifies the schedule and processor allocation
- setMemoryMap: Affine mapping to memory location
- setParallel: Loop parallelization, Parallel dimensions

## Double Max-Plus Computation - Base Schedule

## - Base Double Max-plus Schedule:

- $\left[\mathrm{i}_{1}, \mathrm{j}_{1}, \mathrm{i}_{2}, \mathrm{j}_{2} \rightarrow \mathrm{j}_{1}-\mathrm{i}_{1}, \mathrm{j}_{2}-\mathrm{i}_{2}, \mathrm{i}_{1}, \mathrm{i}_{2}, \mathrm{k}_{1}, \mathrm{k}_{2}\right]$
- Allows maximum parallelization
- Lot of data movements between different levels of caches
- Loop carried dependency. No vectorization since $\mathrm{k}_{1}$ and $\mathrm{k}_{2}$ loops are inside

## Double Max-plus Decomposition

- Base schedule: $\left[i_{1}, j_{1}, i_{2}, j_{2} \rightarrow j_{1}-i_{1}, j_{2}-i_{2}, i_{1}, i_{2}, k_{1}, k_{2}\right]$
- Pulling $\mathrm{k}_{1}$ loop outside of the inner three dimension decomposes the double max-plus operation to multiple matrix instance of max-plus operation

- A series of matrices $\left(\mathrm{i}_{1}, \mathrm{k}_{1}\right)$ to $\left(\mathrm{k}_{1}+1, \mathrm{j}_{1}\right)$
- Better schedule

- Better schedule: $\left[i_{1}, j_{1}, i_{2}, j_{2} \rightarrow j_{1}-i_{1}, i_{1}, k_{1}, i_{2}, j_{2}, k_{2}\right]$
- Schedule with auto-vectorization: $\left[i_{1}, j_{1}, i_{2}, j_{2} \rightarrow j_{1}-i_{1}, i_{1}, k_{1}, i_{2}, k_{2}, j_{2}\right]$
- Allows tiling of the inner three dimensions $\left(\mathrm{i}_{2}, \mathrm{k}_{2}, \mathrm{j}_{2}\right)$
- Now, we can parallelize the $i_{1}$ or $i_{2}$ dimension

## Scheduling $\mathrm{R}_{1}, \mathrm{R}_{2}$, and F-Table

Objective is to find such optimized schedules which increase resource utilization without changing program semantics

| FTable | $\left[\mathrm{i}_{1}, \mathrm{j}_{1}, \mathrm{i}_{2}, \mathrm{j}_{2} \rightarrow X, Y, Z, \quad-\mathrm{i}_{2}, \mathbf{j}_{2}, \quad 0\right]$ |
| :---: | :---: |
| $\mathrm{R}_{1}$ | $\left[\mathrm{i}_{1}, \mathrm{j}_{1}, \mathrm{i}_{2}, \mathrm{j}_{2} \rightarrow X, \quad Y, \quad Z,-\mathrm{i}_{2}, \mathbf{k}_{2}, \mathrm{j}_{2}\right]$ |
| $\mathrm{R}_{2}$ | $\left[\mathbf{i}_{1}, \mathbf{j}_{1}, \mathbf{i}_{2}, \mathbf{j}_{2} \rightarrow X, \quad Y, \quad Z,-\mathbf{i}_{2}, \mathbf{k}_{2}, \mathbf{j}_{2}\right]$ |

## Parallelization Approach

- Coarse-grain
- Multiple F-Table $\left[\mathrm{i}_{1}, \mathrm{j}_{1}\right]$ elements are computed simultaneously
- Poor memory reuse
- Lot of cache misses for double max-plus computations
- Fine-grain
- Multiple cores/threads computing one inner triangle - FTable $\left[\mathrm{i}_{1}, \mathrm{j}_{1}\right]$

- Only $\mathrm{R}_{0}, \mathrm{R}_{3}$, and $\mathrm{R}_{4}$ computations are parallelized
- Low processor utilization
- Hybrid Schedule
- We use the fine-grain parallelism for $\mathrm{R}_{0}, \mathrm{R}_{3}, \mathrm{R}_{4}$ and the coarse-grain parallelism for F -Table, $\mathrm{R}_{1}, \mathrm{R}_{2}$

## Memory Optimization

- Memory-overhead of ALPHAZ generated code is $\mathrm{M}^{2} \times \mathrm{N}^{2}$
- However, we only need one-fourth of that memory. Not too problematic
- But reduction variables also take up memory space by default, which is wasteful
- Each inner triangle requires 5 2-D array for each reduction variables to be active in memory for each thread
- $R_{0}, R_{3}$ and $R_{4}$ are always computed before final F-table update
- Can share the memory with F-Table
- Single row of an inner triangle is required for $\mathrm{R}_{1}$ and $\mathrm{R}_{2}$ to keep up with the F-Table update

## Results

Performance Goal

- We use Xeon E5-1650v4 to present our optimization result
- Theoretical max-plus machine peak is about 346 GFLOPS

| CPU type | Frequency | Number of <br> Cores | Level-1 <br> (KB) | Level-2 <br> (KB) | Level-3 <br> (shared) <br> (MB) | Theoretical Max <br> Plus Peak <br> (GFLOPs) |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| CPU - XeonE5-1650v4 | $6 \times 3.6 \mathrm{Ghz}$ | 6 | $6 \times 32$ | $6 \times 256$ | 15 MB | 346 |

- Arithmetic intensity of BPMax $1 / 6$
- 2-arithmetic operations for 3-single-precision memory operations
- Based on the roofline model, this translates to 329 GFLOPS for programs with similar arithmetic intensity
- Streaming Bandwidth
- BPMax data access pattern $-\mathrm{Y}=\max (\mathrm{a}+\mathrm{X}, \mathrm{Y})$
- Micro-benchmark estimation for the attainable L1 streaming bandwidth
- 120 GFLOPS for 6 threads

Xeon E5-1650v4 Roofline

Micro benchmark for $Y=\max (a+X, Y)$

## Double Max-plus Improvements

- Coarse-grain parallelization performs very poorly
- Generates a lot of data movement between different levels of cache and makes the program slower
- Fine-grain parallelization performs better
- There is a minor difference between computing the
 before moving to the next
- Tiling approach improves locality, maintains automatic vectorization
- Attains 117 GFLOPS with the tiling transformation. $97 \%$ of our microbenchmark target
- Tile dimensions of $(32 \times 4 \times \mathrm{N})$ and $(64 \times 16 \times \mathrm{N})$ are used for presenting the performance and speedup comparison
- $(32 \times 4 \times N)$ is restricted for sequence length up to 2048

## BPMax Improvements

- Coarse-grain version performs worst
- Severe impact on double max-plus computation
- Fine-grain version performs better
- Hybrid parallelization approach highlighted in green performs better than the coarse and fine-grain version
- Tiled version of the hybrid schedule highlighted in dark blue performs best
- It achieves $100 \times$ speedup for longer sequence lengths with 6 threads
- The improvement for the tiled version mainly comes from the optimization of $\mathrm{R}_{0}, \mathrm{R}_{3}, \mathrm{R}_{4}$
- The tiled version of the program reaches around 76 GFLOPS for moderate-size sequences
- It is almost $60 \%$ lower than the best double max- plus version of the same sequence
- Our analysis shows that $R_{3}$ and $R_{4}$ are almost free since those get computed along with the $R_{0}$
- The other two $\Theta\left(M^{2} N^{3}\right)$ computations $-R_{1}$ and $R_{2}$ severely affect the overall performance.

## Effect of Hyper-Threading and Tile Size

- Hyper Threading Effect
- Minimal (3-5\%) improvement with hyper-threading over six threads

- Effect of Tiling $\left(\mathrm{i}_{2} \times \mathrm{k}_{2} \times \mathrm{j}_{2}\right)$ Parameters
- Cubic tiles perform poorly
- We observe the best result when $\mathrm{j}_{2}$ is not tiled
- Due to the streaming effect

Effect of hyper-threading on tiled double max-plus performance

Tile dimension
Effect of tiling parameters ( $\mathrm{i}_{2} \times \mathrm{k}_{2} \times \mathrm{j}_{2}$ ) on double max-plus performance( sequence length $-16 \times 2500$ )

## Conclusions \& Future Directions

- We demonstrate the optimization process of a complete RRI program using polyhedral transformations
- Achieve significant performance improvements
- Tiling improves the performance of the most dominant part of the computation
- Inner reductions are still inefficient, which limit the overall performance improvement.
- These computations are difficult to tile
- Double max-plus operation remains bandwidth-bound even after tiling transformation
- Indicates that an additional level of tiling at the register level is required to make the program compute bound and improve performance
- Distribute the computation over a cluster using MPI
